The Digital Computer as a Musical Instrument

A computer can be programmed to play "instrumental" music, to aid the composer, or to compose unaided.

M. V. Mathews

With the aid of suitable output equipment, the numbers which a modern digital computer generates can be directly converted to sound waves. The process is completely general, and any perceivable sound can be so produced. This potentiality of the computer has been of considerable use at the Bell Telephone Laboratories in generating stimuli for experiments in the field of hearing, and for generating speech sounds and connected speech in investigations of the factors which contribute to the intelligibility and naturalness of speech.

The quality of sound is of great importance in two fields—that of speech and communication and that of music. Our studies at the Bell Laboratories in the first of these fields have led us, over the past few years, to related studies in the production of musical sounds and their organization into mu-

chine for composing music. It can either compose pieces based entirely on random numbers generated by itself or it can cooperate with a human composer. It can play its own compositions.

Here I first describe the process for converting numbers to sounds, then I describe a program for playing music. Next I consider a psychoacoustic problem which is typical of those posed in attempts to make more interesting sounds. Finally, I look to the future, to the time when the computer is itself the composer.

Sound from Numbers

How can the numbers with which a computer deals be converted into sounds the ear can hear? The most general conversion is based upon the use of the numbers as samples of the

example, by running our computer at a rate of 30,000 numbers per second, we can generate sound waves with frequencies from 0 to 15,000 cycles per second. Waves in this frequency range are about the only ones the human ear can perceive.

The signal-to-quantizing-noise ratio of the sound wave depends on the accuracy with which the amplitudes of the pulses are represented. Computers deal with a finite number of digits and, hence, have limited accuracy. However, the computer limits are more than sufficient acoustically. For example, amplitudes represented by four-digit decimal numbers, are accurate to within 1 part in 10,000, an accuracy which represents a signal-to-noise ratio of 80 decibels; this is less noise than the ear can hear, and less noise than would be introduced by any audio equipment, such as the best tape recorder.

The sampling process just described is theoretically unrestricted, but the generation of sound signals requires very high sampling rates. The question should immediately be asked, "Are computers of the type now available capable of generating numbers at these rates?" The answer is "Yes," with some qualifications. A high-speed machine such as the I.B.M. 7090, using the programs described later in this article, can compute only about 5000 numbers per second when generating a reasonably complex sound. However, the numbers can be temporarily stored on one of the computer's digital magnetic tapes, and this tape can subsequently be replayed at rates up to 30,000 numbers per second (each number being a 12-bit binary number).

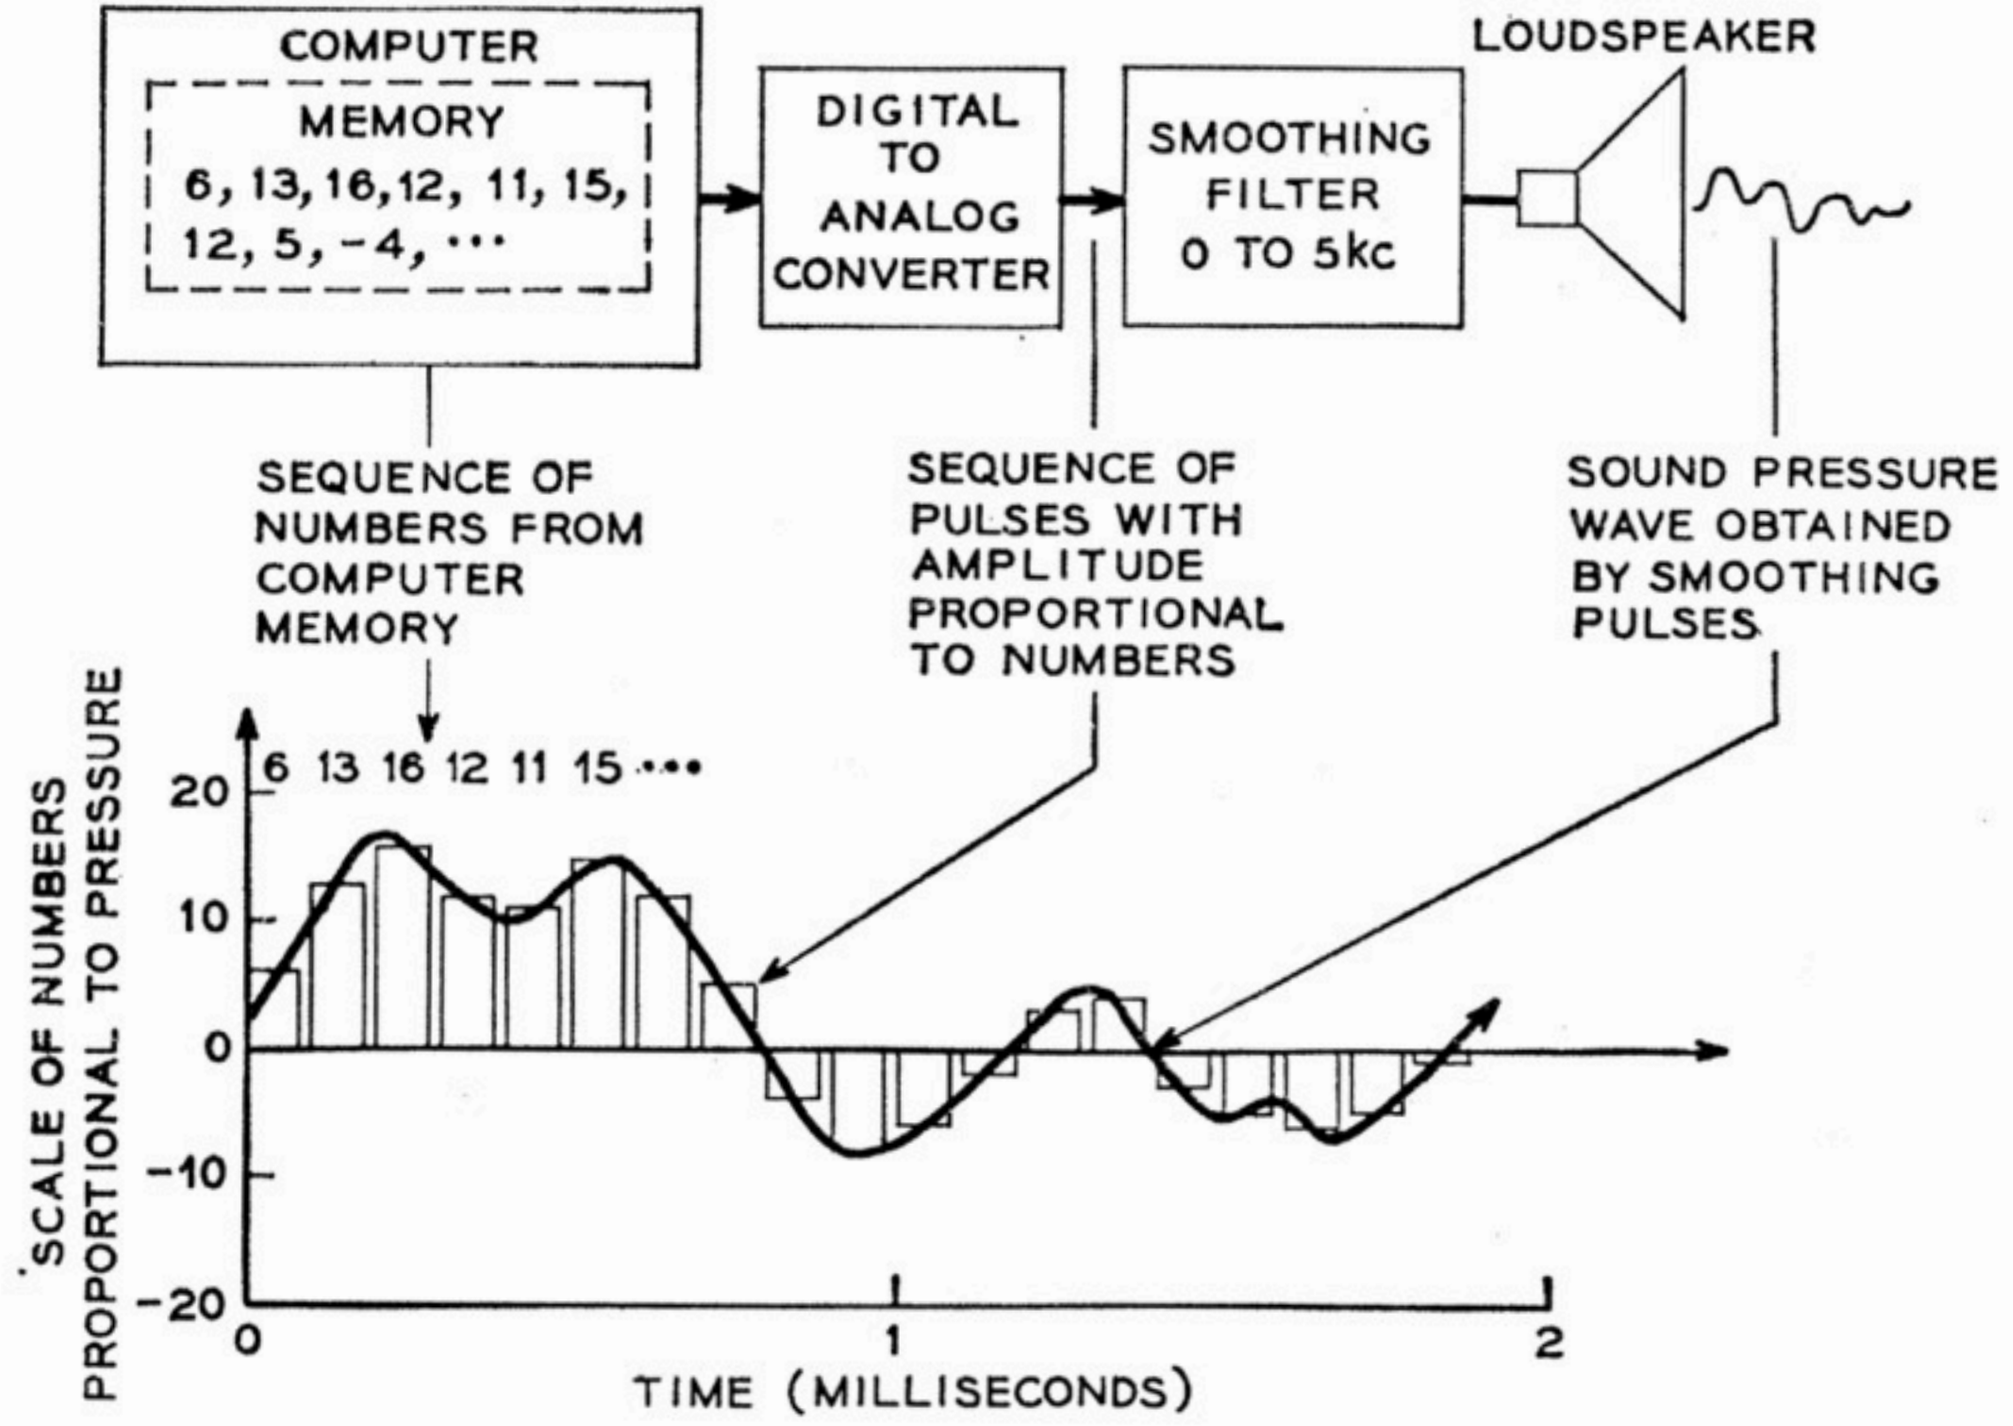

Fig. 1. Schematic diagram depicting the conversion of a sequence of numbers stored in a computer memory to a sound pressure wave form. The sampling rate is 10,000 numbers per second to yield a bandwidth of 5000 cycles per second for the sound wave.

Table 1. A typical computer score. The corresponding conventional score is shown in Fig. 3.

Operation code	Instrument No.	Starting time (sec)	Duration (sec)	Loudness (arbitrary units)	Frequency (cy/sec)	Periodic vibrato		Random vibrato	
						Amplitude (cy/sec)	Frequency (cy/sec)	Amplitude (cy/sec)	Bandwidth (cy/sec)
Play	1	0.0	0.25	1	466	0	0	7.0	6
Play	1	.5	.25	3	698	0	0	10.5	7
Play	1	1.0	.125	5	698	0	0	10.5	7.5
Play	1	1.5	.125	7	698	0	0	10.5	8
Play	1	2.0	.25	9	932	0	0	14.0	8.5
Play	1	2.25	.125	10	784	0	0	11.7	9
Play	2	0.5	.50	1	116.5	1.7	6	0	0
Play	2	1.5	.25	5	156	2.3	7	0	0
Play	2	2.0	.125	10	233	3.5	8	0	0

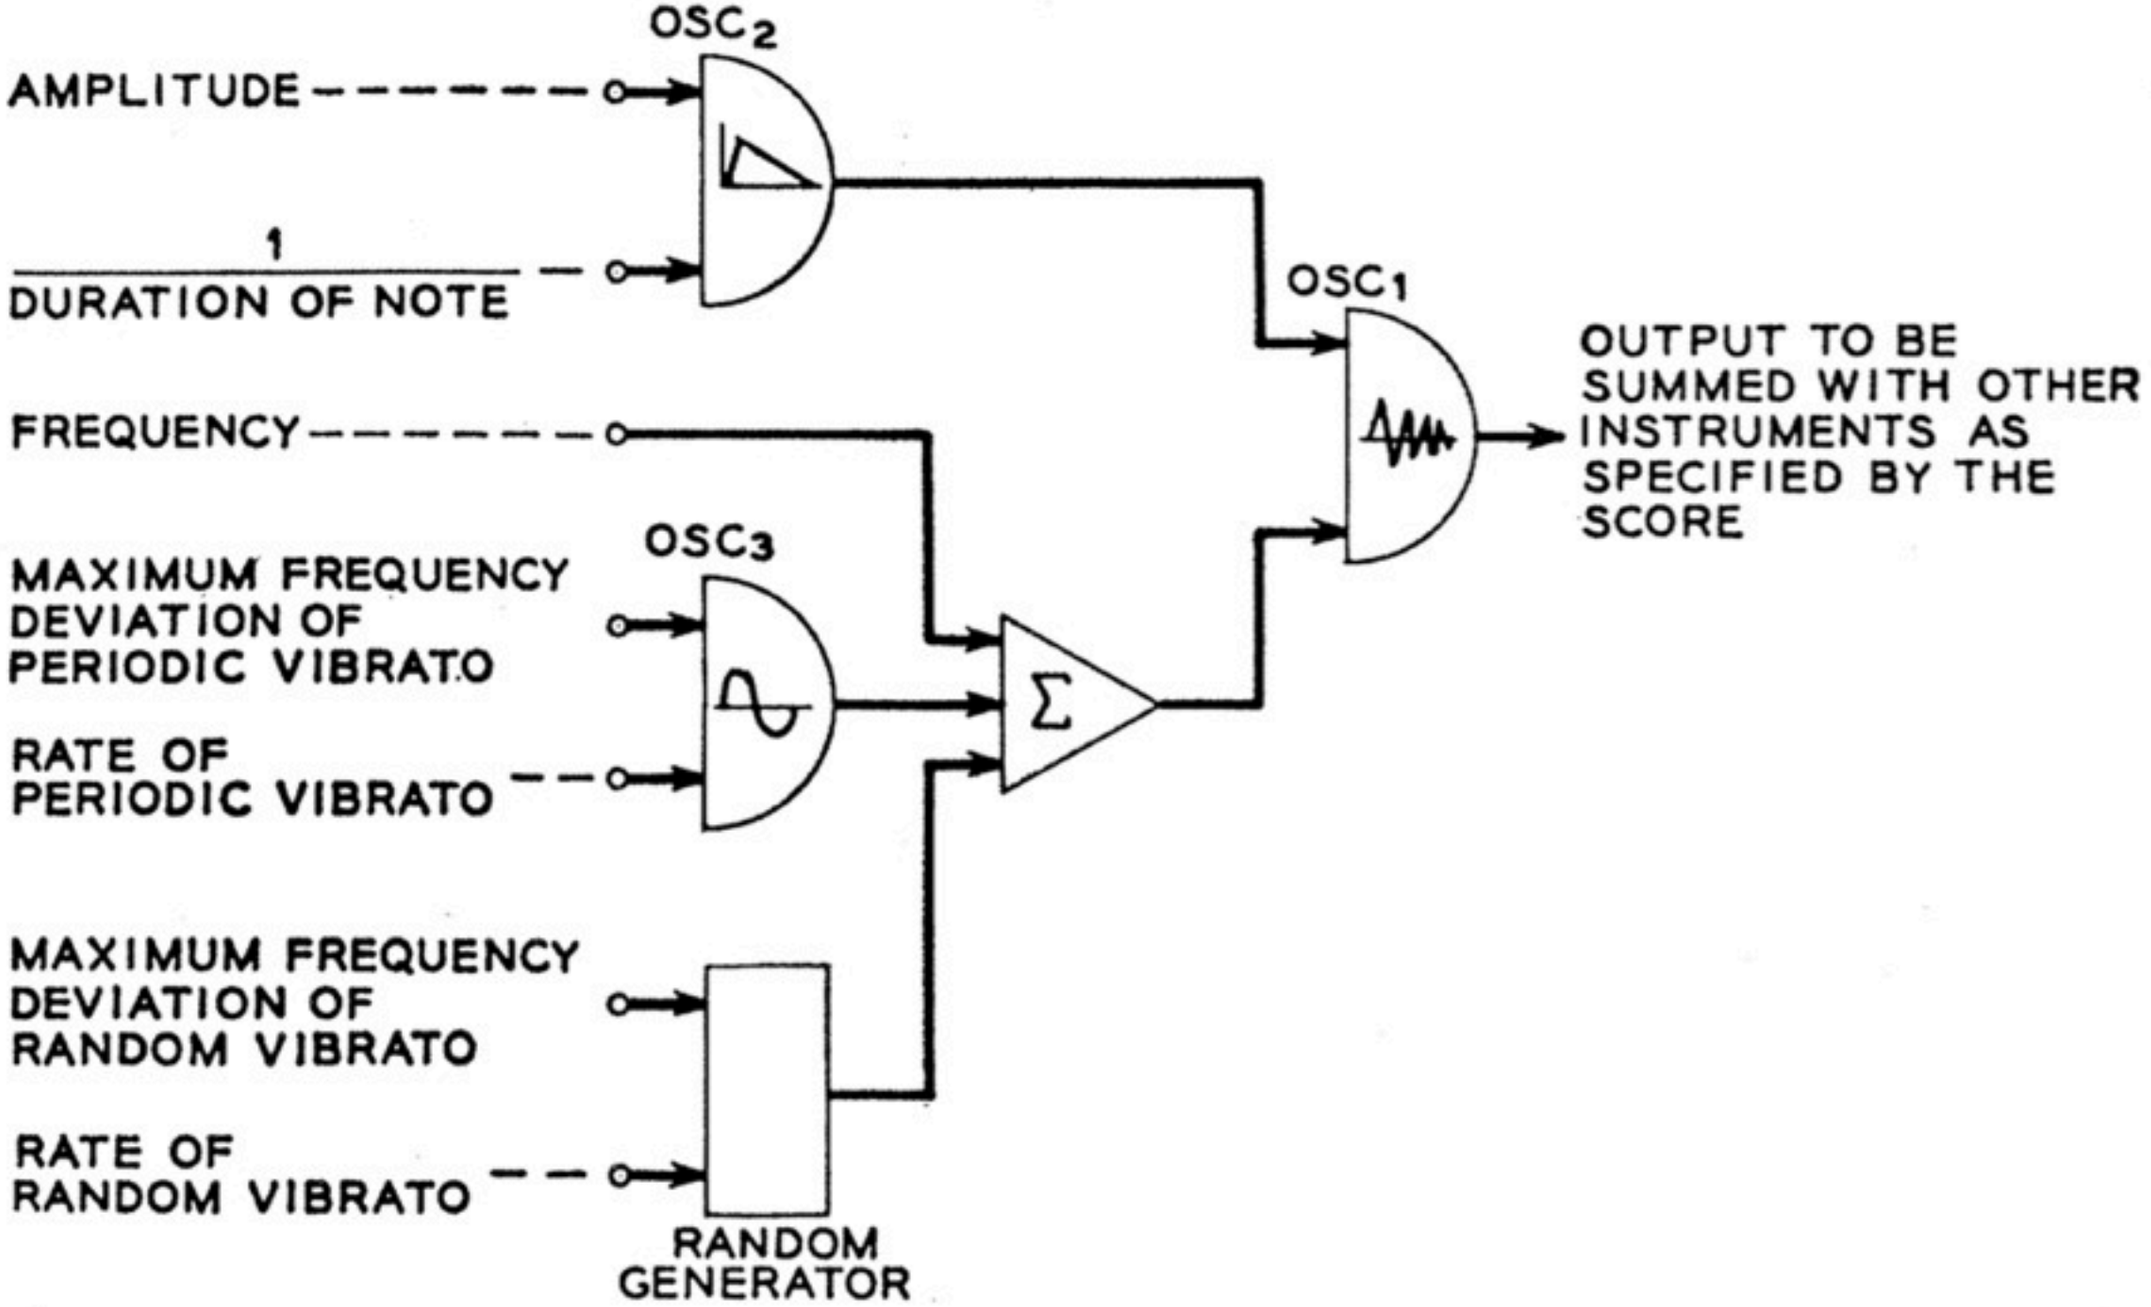

Fig. 2. Schematic diagram of a typical instrument-unit in the computer orchestra. The diagram represents a section of the computer program. In order for the computer to produce a note, numerical values for the note parameters shown at the left of the diagram are stored in the program. The program then generates samples of the sound pressure wave form.

Programmable Music.

Live-coding & musical exploration

Overtone is an Open Source toolkit for creating synthesizers and making music. It provides:

* A Clojure API to the SuperCollider synthesis engine
* A growing library of musical functions (scales, chords, rhythms, arpeggiators, etc.)
* Metronome and timing system to support live-coding and sequencing
* Plug and play midi device I/O
* Simple Open Sound Control (OSC) message handling
